PairesS adicionaram outro elemento diferente do game". Estratégia se BlackJacker 101 pix sportsbet io
The " $21+3$ " blackjack side bet is based on examining the player's two cards and the dealer's up-card. If 6 the three cards form a flush, straight, three-of-a-kind or straight flush, the player wins. In the original version, the payout 6 for each of these was 9 -to-1. With this pay table, the game has a house edge of $3.2386 \%$. Recently, new 6 pay tables have been introduced that have higher house edges and greater volatility.
The point of attack I considered is to 6 target flushes. Any strong imbalance in the suits favors the player. For example, consider a situation where there are 40 6 cards, 10 of each suit. Without going into the math, the number of ways of making a three-card flush is 6480 . Now, take those same 40 cards, and assume they are distributed $15,10,10,5$. Then the number of 6 three-card flushes is 705 . The more unbalanced the distribution of suits, the more the edge swings towards the player.
To make 6 use of
this, it is necessary to keep track of the number of cards in each suit that remain in 6 the shoe. This can be accomplished by a team of counters, each keeping track of one of the suits (or 6 by a mentally gifted solo counter). The counters then compute the difference between the most abundant and least abundant suits. 6 This difference is then turned into a true count, and if that true count is sufficiently large, the player has 6 an edge.
I created a simulation to model using this system on a six-deck shoe game
dealt to 52 cards and 6 simulated one hundred million $(100,000,000)$ shoes. This work showed that a counter can gain an edge on approximately $3.5 \%$ of 6 the hands dealt ( 1.75 hands per shoe). The counter should make the $21+3$ wager whenever the true count is 86 or higher. The average edge when the wager is made will be just over $5 \%$. If the table limit isR\$25, 6 then a counter playing heads-up can earn aboutR\$2.20 per shoe. The new pay tables were not evaluated.
As an experiment, I 6 shuffled one hundred thousand
$(100,000)$ shoes and computed the edge at the point when there were 100 cards remaining in 6 the shoe. The result of this simulation was an average house edge of $3.247 \%$, which is close to the theoretical 6 value of $3.239 \%$. More interesting was that the standard
deviation of the house edge was $3.57 \%$. It follows that a 6 player edge is 0.910 standard deviations above the mean. Therefore, the player will have an edge on about $18.14 \%$ of 6 the shoes at that point. The trick is knowing which ones. My simulation gave a maximum player edge of $23.71 \% 6$ and a maximum house edge of $13.55 \%$.
There are two reasons that
APs will not target $21+3$ with this system. The 6 first is its complexity, the second is the low return. However, there is another approach that may be significantly stronger.Consider 6 a shuffle tracking approach where a slug of cards is identified that is either deficient in one suit or abundant 6 in one suit. In this case, by tracking that slug through a weak shuffle, the AP will have a good 6 opportunity. My knowledge of shuffle tracking is minimal. I cannot say if this is an approach that has been used 6 in practice. Finally, I have not considered if the new pay tables have a similar vulnerability to the 9 -to-1 pay 6 table.
